Programming Languages Proposal

Word Count: 316

The first part of this tutorial ultimately did not show the correct predictions. The original project was an in-browser machine learning model that could predict what something is based off the images provided. Unfortunately, the tutorial that was followed was outdated in its methods and function of using tensor flow. I did not realize this until it was too late. The project did work in terms of structure. First the project uses a python script to turn a Python Keras model into a TensorflowJS usable model: VGG16. Then, we created an html page where one could upload a picture and see predictions of what that picture is. The final part was creating the JavaScript code for doing all the TensorFlow processing. This code was the most complicated as this is where I believe the error occurred. There were several TF errors of it not being in the right tensor shape, etc, even though the tutorial was follow correctly. So this phase of the project was essentially laying the foundation of what will be a bigger project. The next phase of the project will make sure the code fully functions, which will require me deviating from the tutorial. I'll have to code up using another TensorFlow version with newer TensorFlow methods. Other than updating the functionality, I hope to do some sort of preprocessing on the functions to make it more accurate and to run faster. Then, I hope to use Electron or React Native to turn this into a Desktop or Mobile app. I haven't decided which one to use yet. I want to do some experiments and see what would be faster, but I'm leaning towards the Mobile app. I think it would be very cool seeing the in-browser TensorFlow

ability in a mobile app. Finally, I will clean up the UI and make it more dynamic using more JS and React Native.
